

## UPDATES ON IMMUNOTHERAPY FOR PRIMARY BRAIN TUMORS

#### LISA FELDMAN, MD, PHD

Assistant Professor, Department of Surgery Division of Neurosurgery City of Hope National Medical Center

#### **Disclosures**

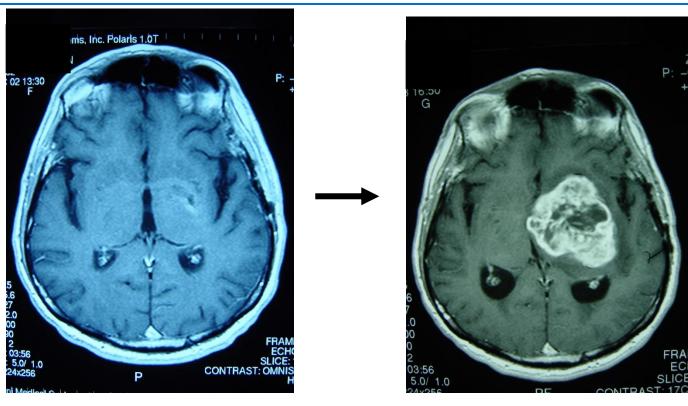

I have nothing to disclose.

## **Glioblastoma (GBM)**

- GBMs are aggressive gliomas, notoriously invasive, rendering complete surgical resection impossible.
- Remains the most common brain tumor in adults, less than 10% patients live beyond 5 years from diagnosis, with median survival less than 20 months.
  - With surgery, chemotherapy, alternating electrical fields, radiation (Alexander & Cloughesy, 2017; Stupp et al., 2017).
- Even in children and young adults, brain tumors remain the leading cause of cancer-related deaths (Pollack, Agnihotri, & Broniscer, 2019)
- Because the blood-brain barrier (BBB) precludes the transmission of many standard therapies, Neuro-oncologists are desperate for novel therapies.

#### **Estimated % of deaths and new cases 2020**

	Male					Female		
	Lung & bronchus	72,500	23%			Lung & bronchus	63,220	22%
	Prostate	33,330	10%			Breast	42,170	15%
	Colon & rectum	28,630	9%	- 7	Γ	Colon & rectum	24,570	9%
ths	Pancreas	24,640	8%			Pancreas	22,410	8%
Deaths	Liver & intrahepatic bile duct	20,020	20,020 6%		Ovary	13,940	5%	
	Leukemia	13,420	4%			Uterine corpus	12,590	4%
Estimated	Esophagus	13,100	4%	- 1		Liver & intrahepatic bile duct	10,140	4%
Ę	Urinary bladder	13,050	4%			Leukemia	9,680	3%
Est	Non-Hodgkin lymphoma	11,460	4%			Non-Hodgkin lymphoma	8,480	3%
	Brain & other nervous system	10,190	3%			Brain & other nervous system	7,830	3%
	All sites	321,160				All sites	285,360	

Estimates are rounded to the nearest 10, and cases exclude basal cell and squamous cell skin cancers and in situ carcinoma except urinary bladder. Estimates do not include Puerto Rico or other US territories. Ranking is based on modeled projections and may differ from the most recent observed data.

©2020, American Cancer Society, Inc., Surveillance Research

According to the Central **Brain Tumor** Registry of the United States (CBTRUS), it is **estimated** that **84,170 new** cases of **primary malignant** and non-**malignant brain** and other CNS **tumors** will be **diagnosed** in the United States in 2021.

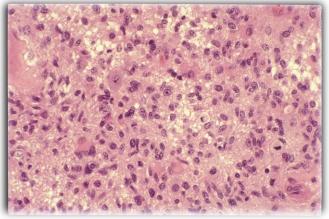

(CBTRUS, 2020)

# **Gliomas: W.H.O. Grading System**

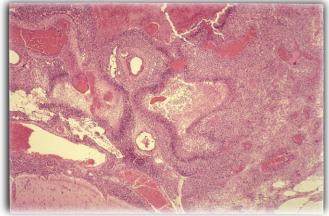

Anaplastic Features	Grade	Incidence		
None	I.	Rare		
Nuclear atypia	Ш	~15%		
Mitosis	III	~30%		
Vascular endothelial				
proliferation	IV	50-60%		
Necrosis	IV			

**Grade III Astrocytoma** 

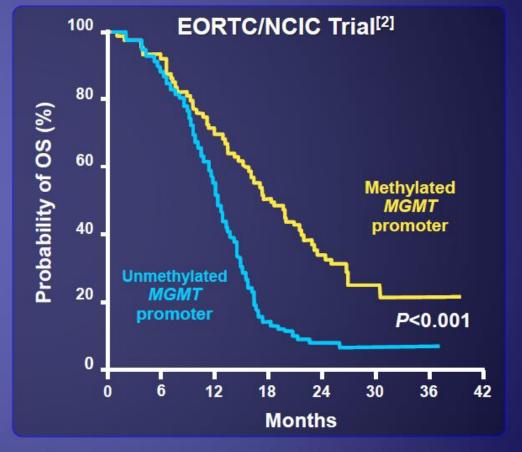

Anaplastic Oligodendroglioma

Grade IV Astrocytoma Glioblastoma (GBM)

## MGMT (O<sup>6</sup>-Methylguanine-DNA Methyl Transferase)

- MGMT is an enzyme that repairs damage to DNA from alkylating agents.
- Methylation (inactivation) of the MGMT gene results in lower levels of MGMT in tumor.
- Methylated MGMT occurs in 50% of GBM pts
  - A prognostic factor for GBM patients
  - A predictive factor for response to treatment with an
  - alkylating agent (temozolomide, BCNU)

(Hegi et al., 2005)

#### **Select Biomarkers in Glioblastoma**

	Prognostic Association		
Biomarker	Prognostic Indication	Favorable	Poor
MGMT methylation <sup>[1]</sup>	<ul> <li>Methylated in 30%–60% of cases</li> <li>Methylated <i>MGMT</i> increases response to chemotherapy</li> <li>Unmethylated <i>MGMT</i> decreases response to chemotherapy</li> </ul>	1	
IDH1/2 mutations <sup>[2,3]</sup>	<ul> <li>More common in lower grade glial tumors</li> <li>IDH1/2 mutation occurs in approximately 3.7% of primary GBMs versus 73.3% in secondary GBM</li> </ul>	1	
EGFR amplification <sup>[4,5]</sup>	Observed in ~50% of primary glioblastomas		×.
EGFRvIII mutation <sup>[4]</sup>	<ul> <li>EGFR-amplified cells often contain EGFRvIII mutation, which confers constitutive activity</li> <li>30% glioblastoma tumors express EGFRvIII</li> </ul>		*

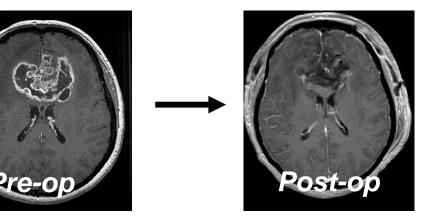

(Johnson et al., 2012; McNamara, Sahebjam, & Mason, 2013; Nobusawa, Watanabe, Kleihues, & Ohgaki, 2009; Preusser et al., 2011; Stupp et al., 2014; Yan et al., 2009)

# Standard Treatments for Glioblastoma

- No curative options!
  - Goal: Preserve QOL, neuro function and extending survival (Henriksson, Asklund, & Poulsen, 2011)
- Surgery
  - Pathological diagnosis
  - Maximal safe resection can increase survival
  - Alleviation of mass effect (pressure)
  - Reverse or prevent neurological deficit
  - Avoid causing neurological deficits

(Dandy, 1928)

# **Standard Treatments for Glioblastoma**

## Radiation

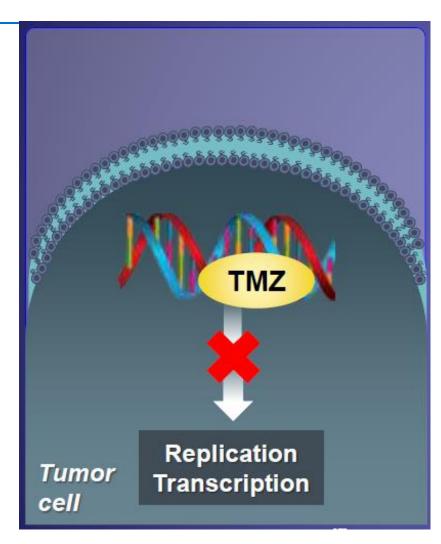

- •For 6 weeks, focal brain RT
- •Side effects: hair loss, fatigue, cognitive decline

## Chemotherapy

- •**Temozolomide (TMZ):** oral and IV alkylating agent (during RT and for at least 6 months afterwards)
- •Alkylating agents bind to DNA, impair replication/transcription
- $\rightarrow$  cell death (Fu, Calvo, & Samson, 2012)
- •TMZ crosses BBB and is spontaneously converted into active metabolite in CNS (Agarwala & Kirkwood, 2000)

#### Toxicity

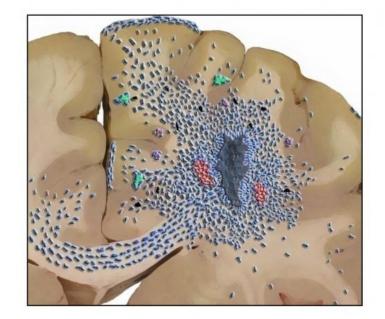

- Most common: constipation, nausea
- •Dose-limiting: neutropenia (14%), thrombocytopenia
- (19%)

(Wesolowski, Rajdev, & Mukherji, 2010)

## **Treatment Challenges**

- 1. Brain tumors are <u>invasive</u>
- 2. Standard therapies (surgery, radiation, and chemotherapy) may cause <u>brain injury</u>
- 3. The <u>blood-brain barrier</u> prevents penetration of most chemotherapies into the brain
- 4. Tumor <u>heterogeneity</u>
- 5. <u>Immunosuppressive</u> microenvironment

Tumor cells have cleverly evolved to evade their destruction by the host immune system.

 Immunotherapy (AKA biological therapy, biotherapy or biological response modifier therapy) stimulates the immune system to recognize and target cancer cells and/or lessen treatmentrelated side effects.

 Current immunotherapies are available for breast, hematological, kidney, lung, melanoma, mesothelioma, ovarian, pancreatic, prostate cancers....

# Timeline of oncolytic virus development from glioblastoma therapy

- Oncolytic virotherapy employs viruses with a preserved potential for an active viral life cycle.
- The chief paradigm is tumor-selective conditional viral replication, resulting in lytic tumor cell destruction and release of thousands of viral progeny.
- Newly released viruses go on to infect neighboring tumor cells, theoretically causing and maintaining a wave of virus attack throughout the tumor.

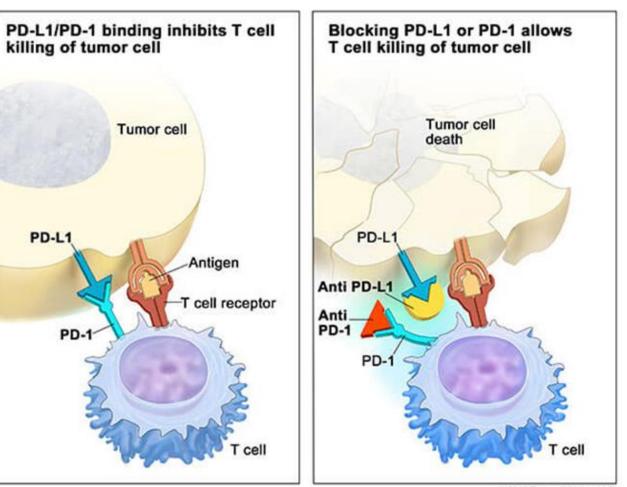

#### (Wollmann, Ozduman, & van den Pol, 2012)

#### Immune checkpoint inhibitors (ICIs):

 Immune checkpoints are molecules on certain immune cells that need to be activated or inactivated to start an immune response.

Some tumors utilize ICIs to evade immune attack

 Programmed cell death protein-1 (PD-1) dampens anti-tumor immune responses (Kamath & Kumthekar, 2018; Simonelli et al., 2018)

## **Chimeric antigen receptor (CAR) T cells**

- CAR T cells were designed over four decades ago to overcome an ineffective immune system by genetically modifying T lymphocytes to recognize and eliminate cancer cells (Gross, Waks, & Eshhar, 1989).
- In this adoptive cell therapy, cells are harvested from patients, modified to target specific proteins expressed by the tumor, and re-introduced into the patient with the goal of destroying tumor cells.
- Shown great promise in blood-borne cancers such as relapsed or refractory B-cell lymphomas by targeting CD19 (Maude et al., 2018; Park et al., 2018).
- Currently FDA-approved for relapsed or refractory diffuse large B-cell lymphoma (DLBCL) and acute lymphoblastic lymphoma (ALL).
  - Detected in CSF

- Tumor heterogeneity:
  - CAR T cells are particularly successful at targeting and destroying B-cell malignancies because these T cells are engineered to bind to a single molecule that is uniformly expressed on the surface of all B-cell derived tumors, CD19.

 GBM tumors are notorious for having intra-tumor, and inter-tumor heterogeneity of cellular, genetic and molecular signatures (Brown, Stylli, Kaye, & Mantamadiotis, 2019; Neftel et al., 2019; Verhaak et al., 2010).

- GBM tumors actively contribute to immune suppression through a host of wellorchestrated strategies to create a T-cell suppressive tumor microenvironment.
  - Microenvironment suppress their activity and proliferation by expressing inhibitory cell-surface molecules (such as PD-L1, CD95) (Ricklefs et al., 2018) or by releasing immunosuppressive tumor-derived soluble factors and cytokines (such as prostaglandin E2, IL6, IL10 and TGFβ) (Hao et al., 2002).

 Microenvironment preferentially promotes trafficking of suppressive cell populations, such as regulatory T cells (Tregs), tumor-associated macrophages, microglia and myeloid-derived suppressor cells (Choi, Maus, June, & Sampson, 2019; Dubinski et al., 2016; Hussain et al., 2006) and creates other physical and metabolic blockades (Mirzaei, Sarkar, & Yong, 2017; Newick, O'Brien, Moon, & Albelda, 2017).

- Cytokine release syndrome (CRS), or the systemic elevation in several cytokines including IL-6 and IFN-γ, is a common toxicity associated with CD19-CAR T cells that is indicative of immunotherapeutic potency (Lee et al., 2014).
- Neurotoxicity (encephalopathy, delirium, seizures, edema) is also a common treatment-related toxicity of CD19-CAR therapy, resulting from increased inflammatory cytokine levels and endothelial dysfunction of the bloodbrain barrier (Gust and Turtle, 2017; Santomasso and Brenjens 2018; Gauthier and Turtle, 2018)
- Avoiding any severe brain inflammation and severe CRS is of utmost importance in GBMs, as increased intracranial pressure in patients already with increased mass effect from tumor can lead to deadly outcomes.
- CAR T cell trials in GBM have thus far reported less severe CRS and neurotoxicity-like adverse events as compared to CAR T cells targeting hematological cancers.
- To give Dex or not??

🕅 Cityof Hope.

 One strategy is to desensitize CAR T cells to steroids is to genetically disrupt the glucocorticoid receptor (Menger et al., 2015), while others use anti-IL6 antibody (O'Rourke et al., 2017) or Bevacizumab (Migliorini et al., 2018) to reduce local inflammation.

A balance is needed in treating CAR T patients with symptomatic brain edema while prioritizing for CAR T cell therapeutic activity, and at City of Hope we do this by limiting dexamethasone to 6 mg in a 24-hour period in our patients.

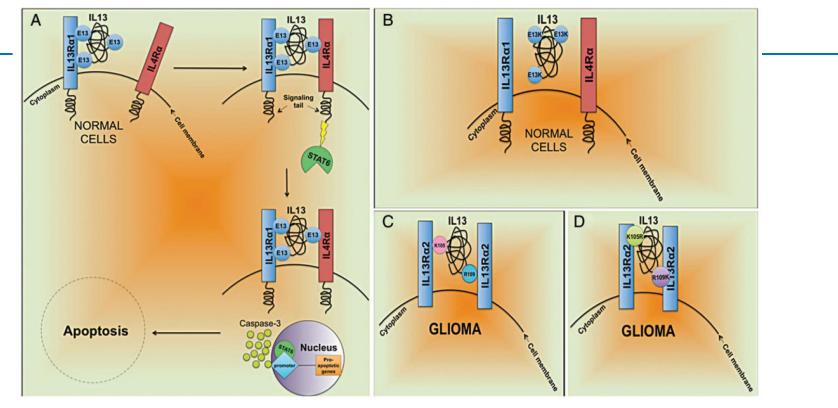

#### **Clinical Studies of CAR-T Cells for Glioblastoma**

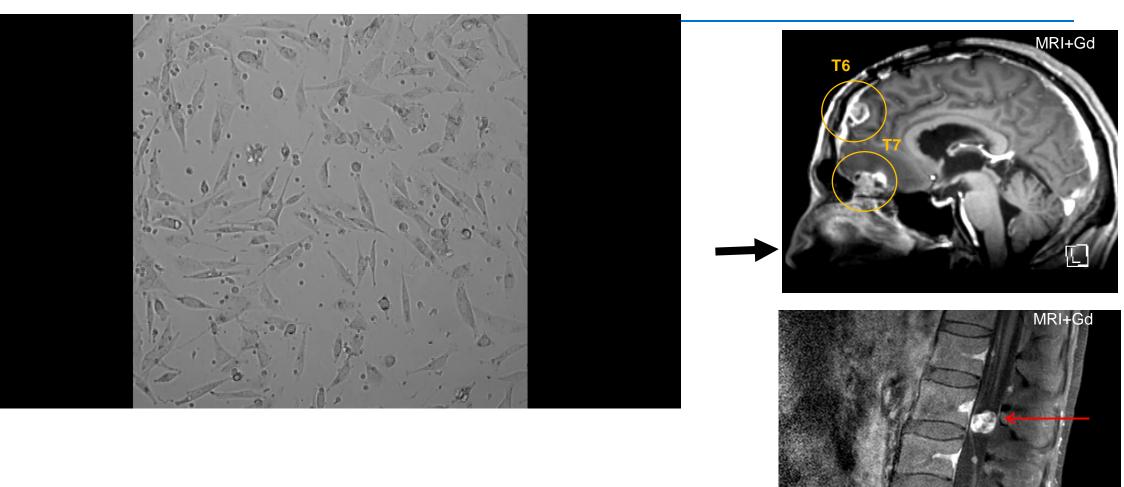

X City Mope.

#### Interleukin 13 Receptor α2 (IL-13Rα2)

- IL-13Rα2 not only blocks the normal apoptotic pathway, but also induces upregulation of STAT3, promotes invasion and metastasis via extracellular signal-regulated kinase/activator protein 1, and promotes tumor immune escape via upregulation of transforming growth factor β (Thaci et al., 2014)
- Expressed in up to 75% GBMs with high variability (Jarboe, Johnson, Choi, Lonser, & Park, 2007; Joshi, Plautz, & Puri, 2000; Liu et al., 2000; Saikali et al., 2007)

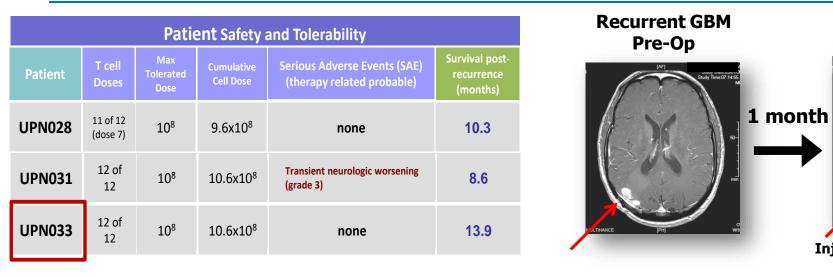

# CAR-T Cells Therapy for Glioblastoma: Laboratory to Clinic

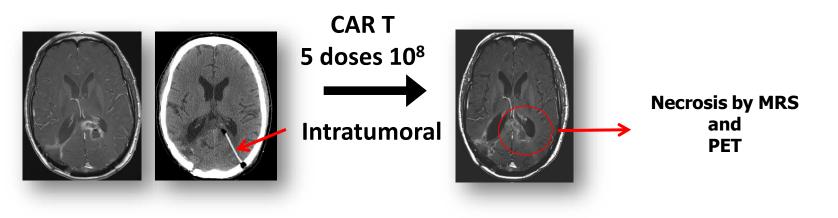

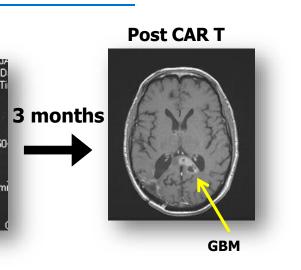

Primary patient-derived gliomas incubated with autologous T cells (captured over 8-12 hrs)

🛣 Cityof Hope.

## Clinical Evaluation of First-Generation Autologous IL13-zetakine T cells Locally injected for the Treatment of GBM

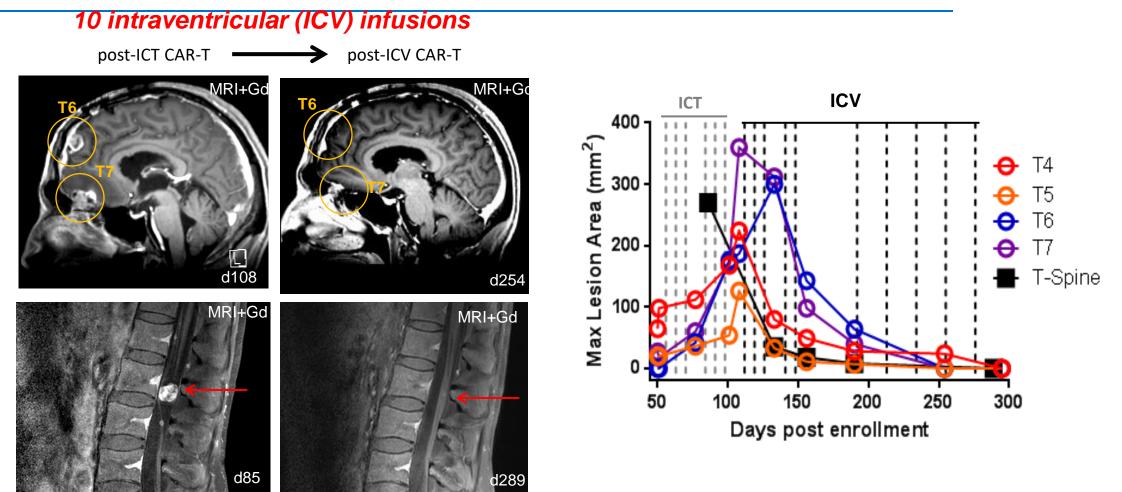

Post-Op
