

### GIVING LIFE TO POSSIBLE

## Background

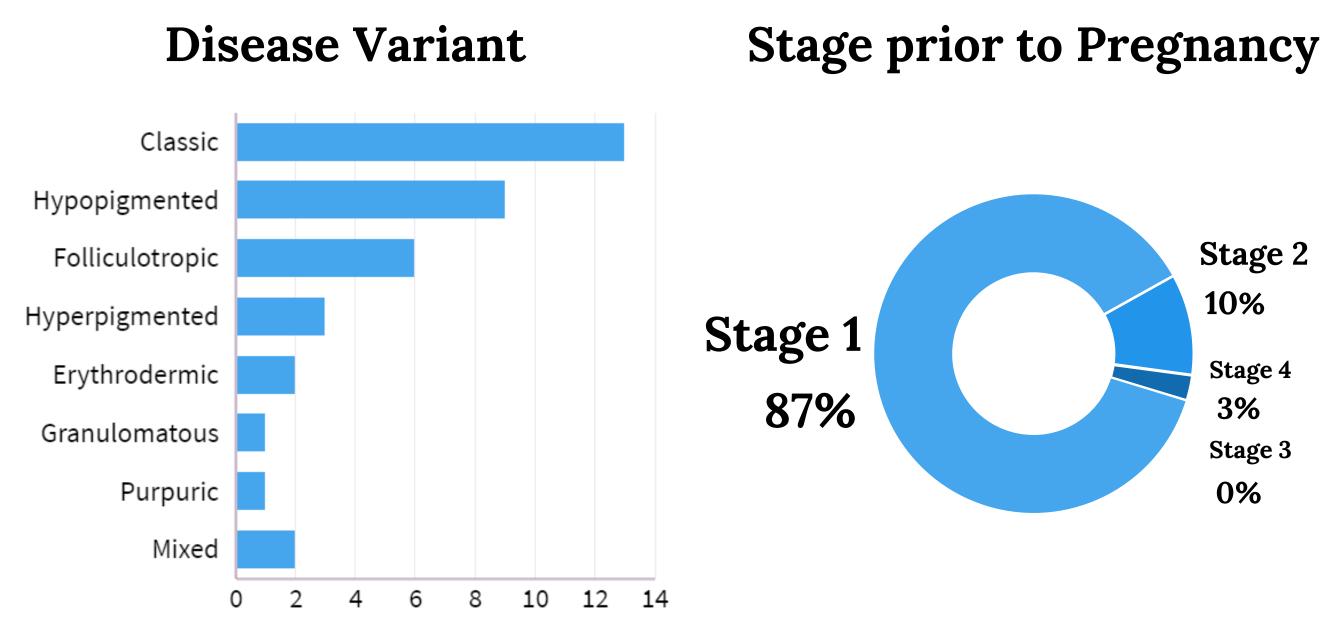

- The immunologic changes of pregnancy may affect the course of mycosis fungoides (MF)
- <u>Primary objective</u>: characterize MF disease activity during pregnancy and in the postpartum period (defined as 1 year after delivery)
- <u>Secondary objective</u>: assess management and overall survival outcomes

# Methods

- Patients evaluated between 1980-2023 were identified from an institutional cutaneous lymphoma database for retrospective review
- Inclusion criteria: patients diagnosed with MF prior to onset of pregnancy. Patient reported changes in disease during and after pregnancy were assessed based on HPI.

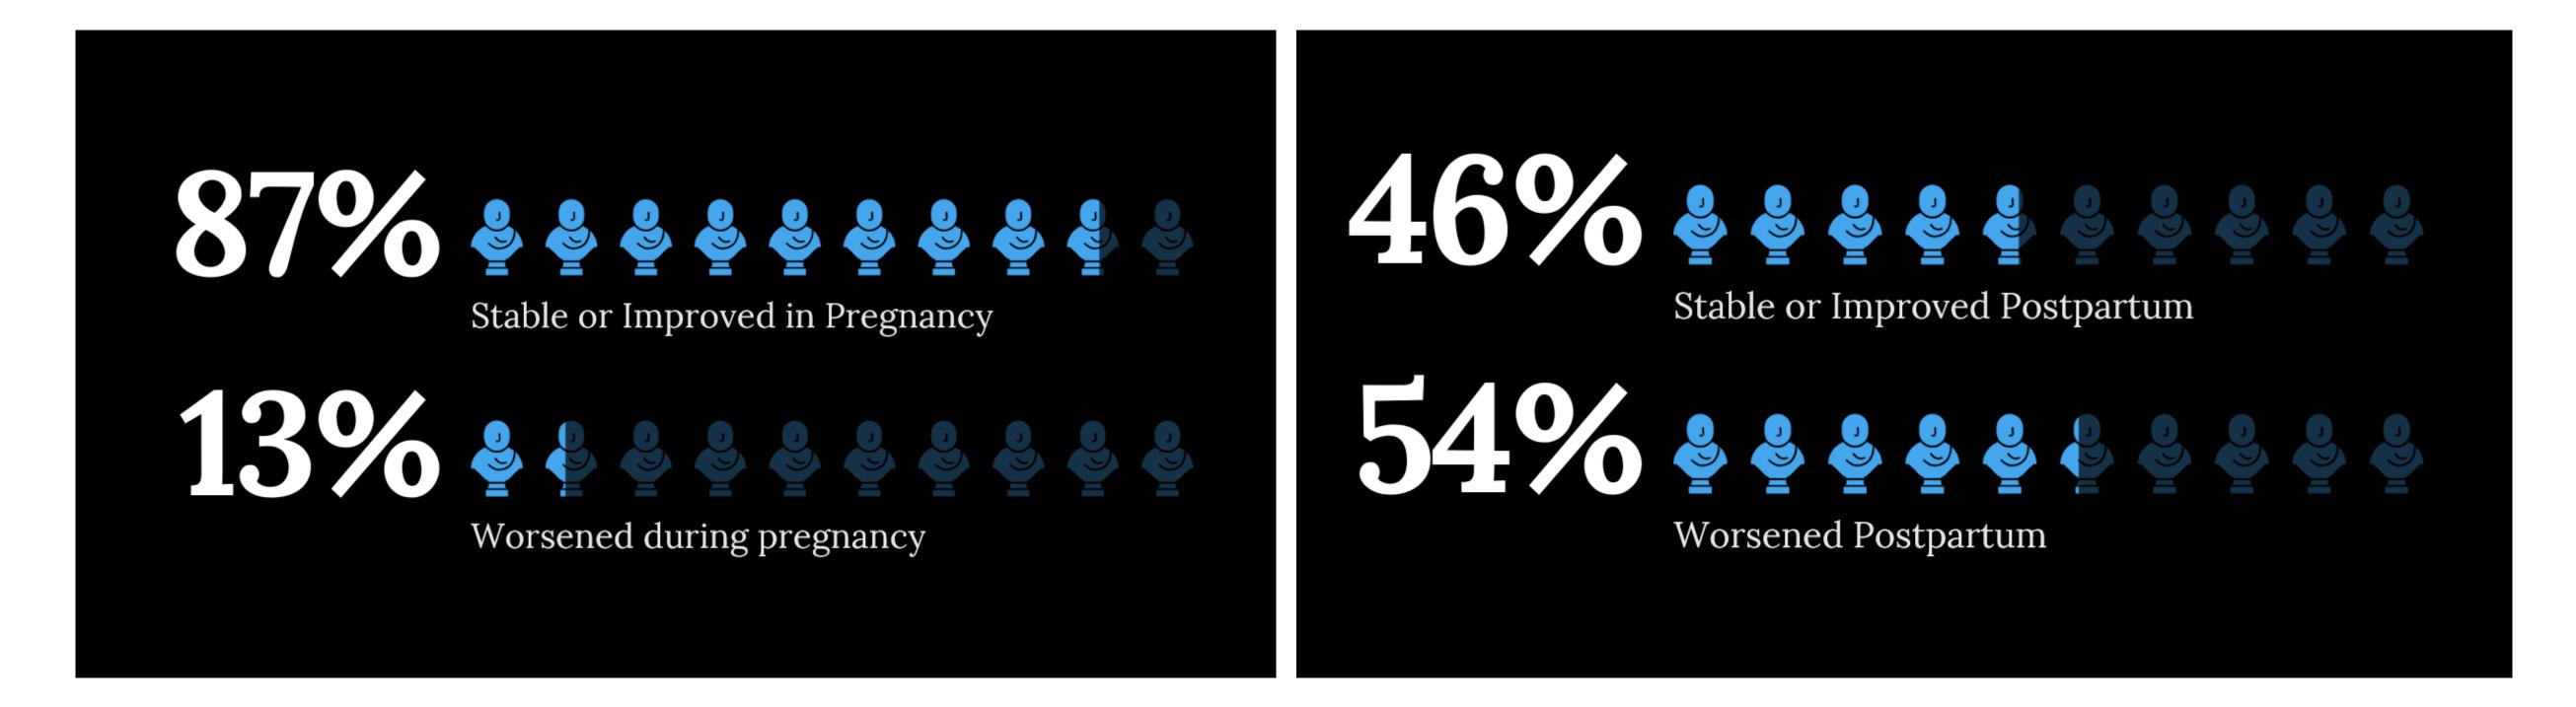

### **Baseline features**

- n = 37 patients evaluated over 39 pregnancies
- Median age at pregnancy: 32 years (range: 18-46 years)

## **Mycosis fungoides in pregnancy: disease activity and outcomes**

Rishabh Lohray BS<sup>1</sup>, Seda Purnak MD<sup>2</sup>, Auris Huen MD<sup>2</sup>, Madeleine Duvic MD<sup>2</sup>, Julia Dai MD<sup>2</sup> <sup>1</sup> Baylor College of Medicine <sup>2</sup>Department of Dermatology, MD Anderson Cancer Center

- immediate postpartum period

- UVB (nbUVB) phototherapy
- Five-year overall survival: 95%

- advancement in stage
- nbUVB phototherapy

### **Disease behavior & pregnancy**

• In total, 54% of patients demonstrated worsening of MF activity in the pregnancy and

• Patients experienced worsening disease more frequently in the postpartum period compared to during pregnancy (54% vs. 13%, p<0.05)

• Advancement in stage was observed in 11% (4/37) patients, all of which occurred in the postpartum period compared to none during pregnancy.

• In 56% (22/39) of pregnancies, patients opted for close monitoring of disease without active therapy; the remaining patients were managed with topical corticosteroids and narrow band

100% of pregnancies (n = 39/39) had viable deliveries.

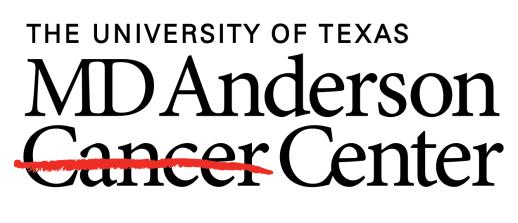

### Conclusions

• In 89% of cases, MF during pregnancy or the postpartum period was characterized by a non-progressive course. Fifty four percent of patients saw worsening skin disease in the pregnancy and immediate postpartum period; however, only 11% demonstrated

• Forty four percent of patients were successfully managed with topical corticosteroids and

• We recommend joint management with a multidisciplinary team, including colleagues in Obstetrics-Gynecology, given complexity of patients and potential for progression
